

VALUE / PROBLEM STATEMENT

A private conversation should lead to a clear agreement.

VINSS gives a client and freelancer one room to discuss work, agree on an offer, review delivery and settle payment on Canton.

The problem

Scope and payment drift apart.. The work is discussed in a messenger, the job lives on a marketplace, and payment has a separate status. Both people must reconcile those records when the scope changes.

Each side needs clarity.. The client needs to review delivery against the agreed terms. The freelancer needs to see whether payment is funded and what remains before settlement.

The product

Join with a link or QR.. Each person connects a Canton wallet. VINSS resolves the signed peer installation and opens an MLS conversation without manual Party or Installation IDs.

Make an offer in the conversation.. Detailed terms travel inside encrypted messages. Canton records the amount, asset, Parties, terms hash and agreement lifecycle.

Connect delivery to settlement.. The payer funds a Token Standard Allocation. The freelancer submits work, the client approves or requests revision, and the freelancer settles after approval.

Why Canton, why now

A shared workflow with selective access.. Canton supplies Party-based contract visibility and Daml authorization. OpenMLS encrypts conversation content. Token Standard Allocations connect the agreement to the payment rail.

Start with a bounded use case.. The current MVP brings these pieces together for direct client work. A small Canton pilot can now test whether people can complete and reuse the workflow.

Current scope. Current scope: Canton, private deals and encrypted groups. Groups have no escrow UI. Dispute/refund handling and cross-device recovery remain unimplemented.
